

# Intracranial Pressure Monitoring

# Monro-Kellie doctrine

- skull
  - closed box, fixed volume
- contents
  - blood, brain and CSF
  - non-compressible fluids

increase in one component  
(brain swelling)

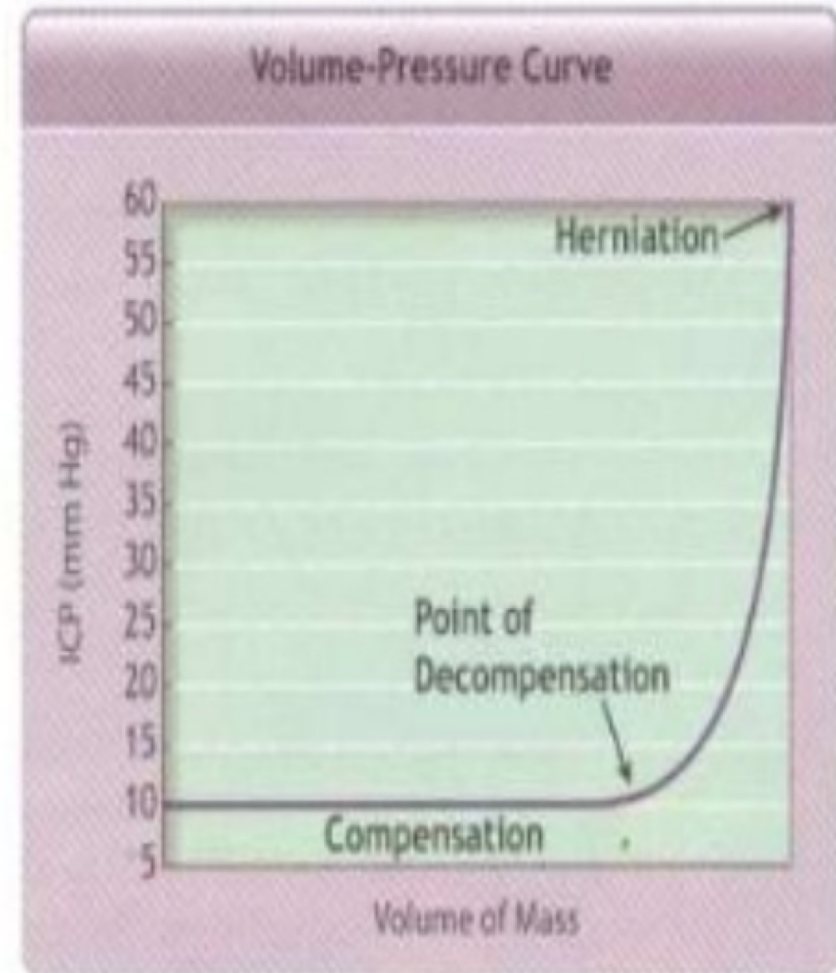

or

addition of new component  
(haematoma)

displaces another component

**' compliance '**

- “compliance reflects the ability of the intracranial system to compensate for increases in volume without subsequent increases in ICP. **When compliance is decreased, even small increases in intracranial volume result in large increases in ICP.**”

$$V_{\text{intracranial vault}} = V_{\text{brain}} + V_{\text{blood}} + V_{\text{CSF}}$$

- Harvey Cushing

- With an intact skull, the sum of brain volume, CSF volume, and intracranial blood volume is constant
- An increase in one component should cause a reduction in one or both of the other two

# Why is ICP Monitoring Important

- Confirm or exclude intracranial hypertension
- Initiate ICP lowering measures as early as possible
- Determine whether intervention is effective
- Especially important in sedated or unresponsive patients

# Indications for ICP Monitoring

- Head injury/TBI
  - GCS < 8
  - Posturing -- flexion/extension
- Subarachnoid hemorrhage
- Stroke
- Intracerebral hematoma
- Hydrocephalus
- Perioperatively: resection of large brain tumors or AVMs when concern for cerebral edema is high and clinical neuro exam is not possible

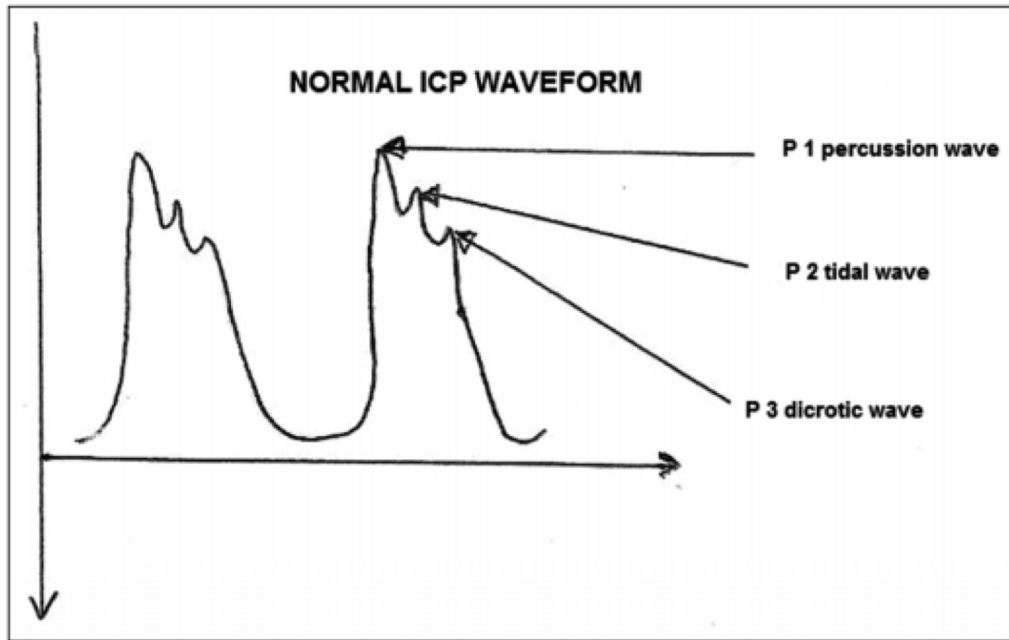

# Dynamics of ICP

- Information that can be derived from ICP monitoring
  - CPP
  - Regulation of CBF and volume

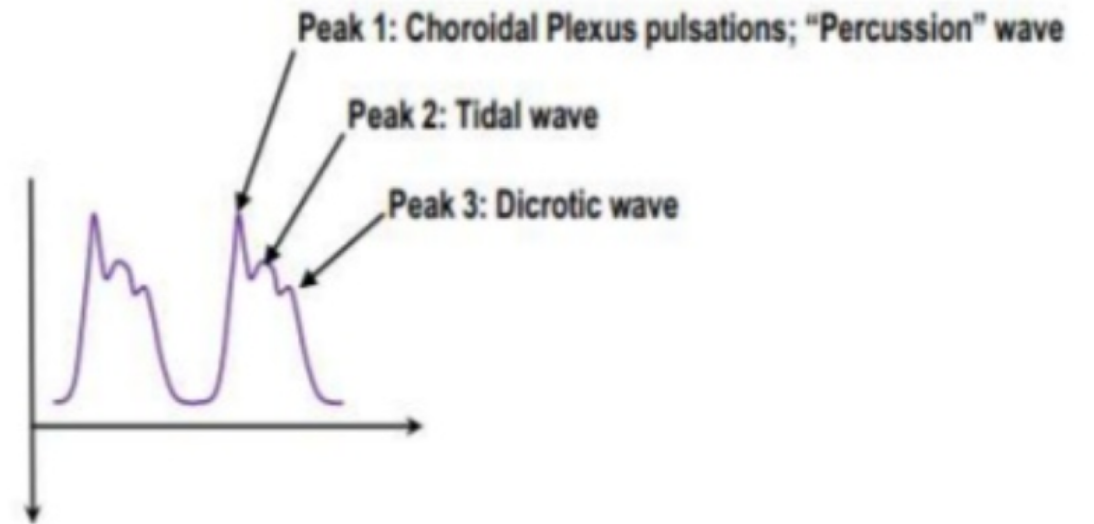

# ICP Waveforms

- P1 = Percussion Wave
  - arterial pulsation
- P2 = Tidal Wave
  - intracranial compliance
- P3 = Dicrotic Wave
  - venous pulsation

Normal ICP waveform		
Peak	Wave	Origin
First large peak	Percussion wave $W_1$ (pulsatile)	Systolic pressure, large intracranial arteries and choroid plexus CBF
Second small peak	Tidal wave $W_2$ (pulsatile)	Central venous wave from right atrium, from brain increased elastance/ decreased compliance
Inverted	Inverted	Miscalibrated monitor
Third small peak	Dicrotic wave $W_3$	Arterial pulse
Expiration	Increases overall wave	Increasing central venous pressure
Inspiration	Decreases overall wave	Decreasing central venous pressure

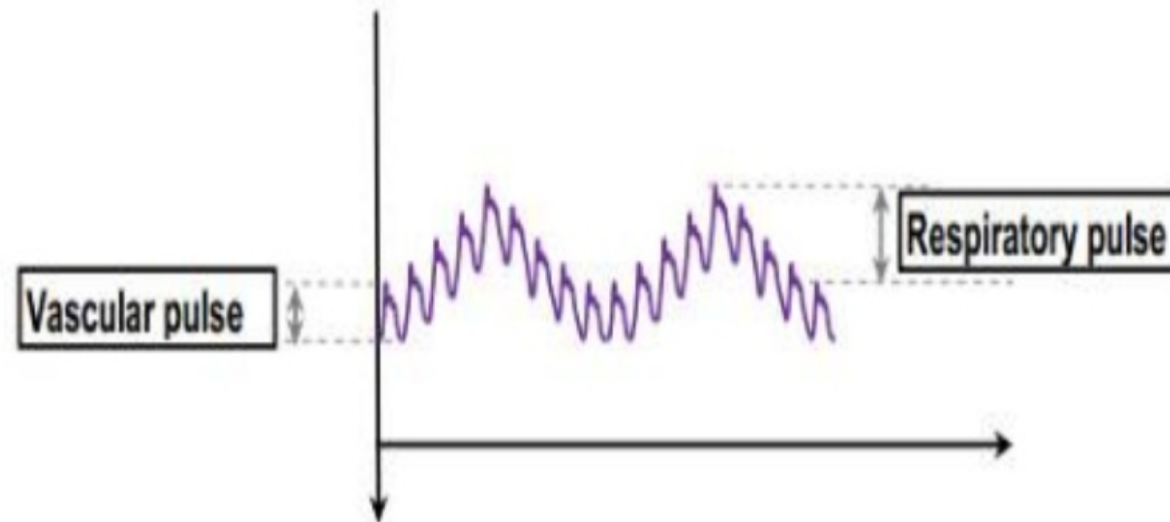

**Figure 3:** Intracranial pressure waveform reflecting three peaks – P1 (correlating with the arterial pulse); P2 (relating to the cerebral compliance); P3 (corresponding to aortic valve closure)

Related to

- Cardiac cycle : within individual waves
- Respiratory cycle : between consecutive waves

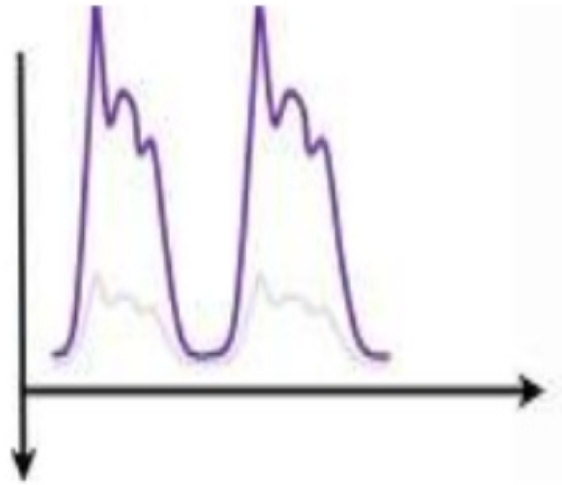

# Flat

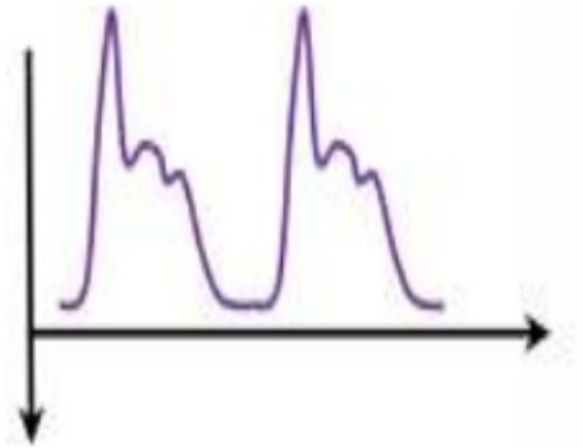

- EVD clogged / kinked
- Patient expired

## ↑/↓ amplitude

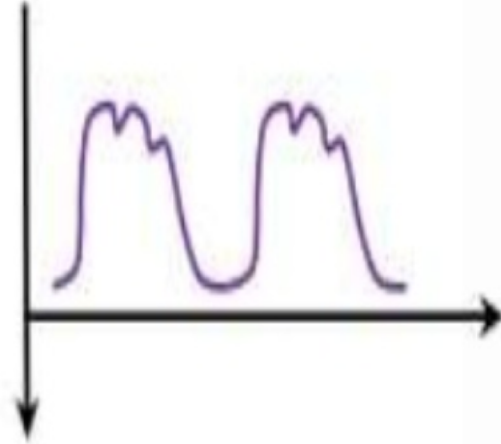

- Increasing CSF volume (or decreased)
- If a large volume of CSF is drained off, the waveform will decrease in amplitude.
- Missing bone flap

## Prominent P1 wave

- The systolic BP is too high

## Diminished P1 wave

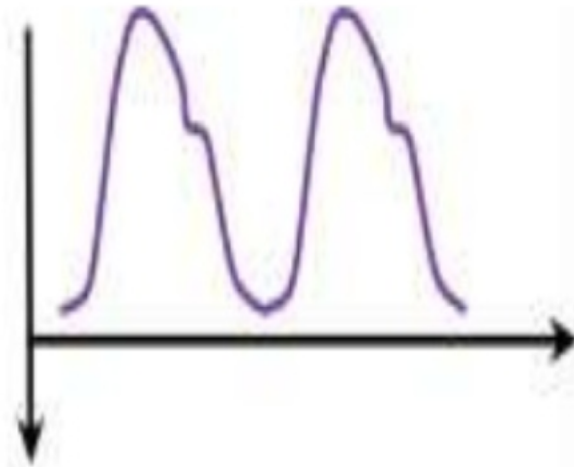

- If the systolic BP is too low, P1 decreases and eventually disappears, leaving only P2.
- P2 and P3 are not changed by this.

## Diminished P2 and P3 waves

- Hyperventilation

## Rounded ICP waveform

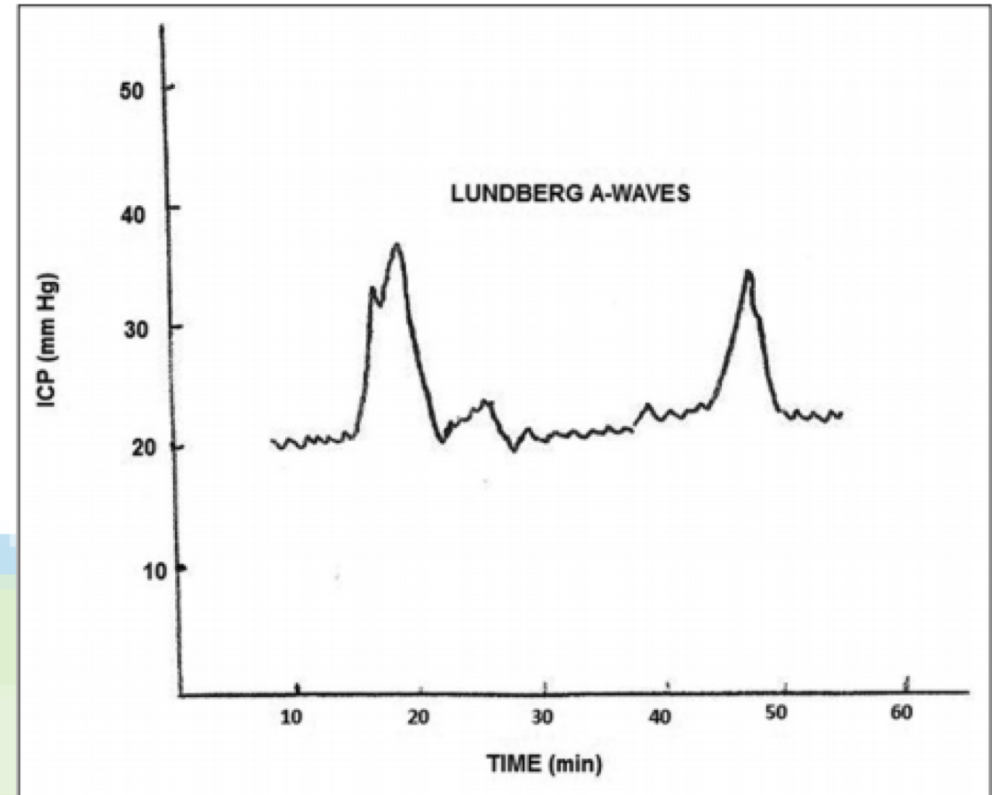

- ICP critically high

# Nils Lundberg & his waves ...

## Lundberg A Waves

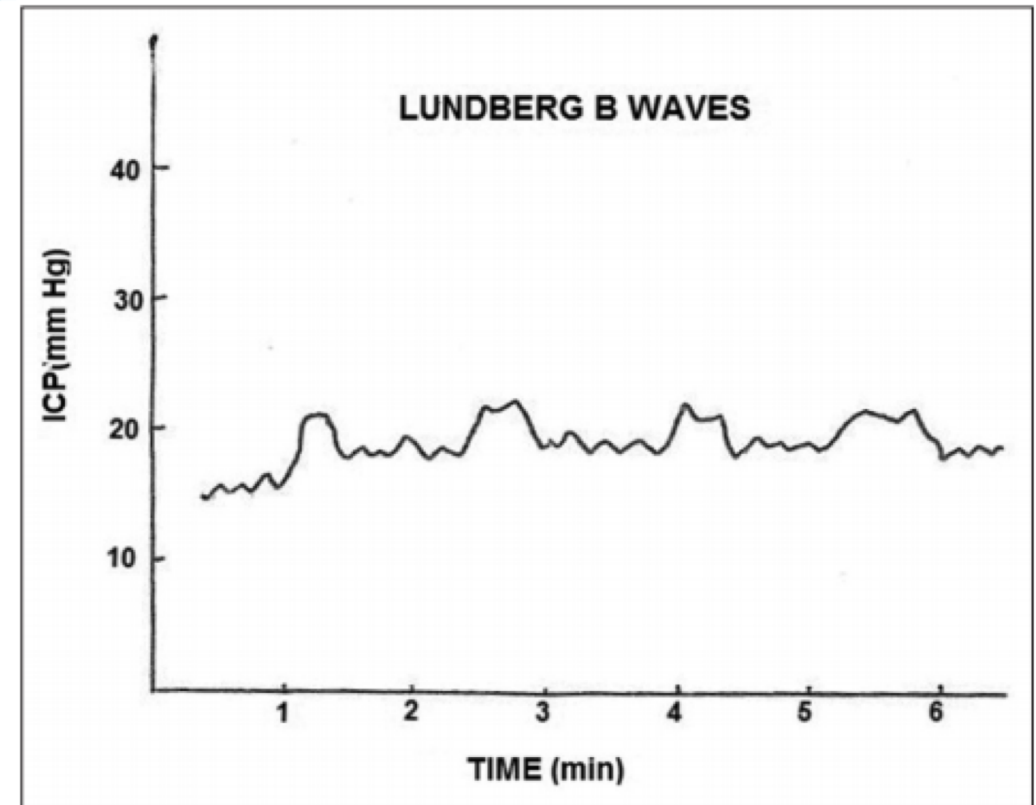

- ICP is increased and IC compliance is decreased, pathological waves appear
- Characteristic of conditions that lead to a reduced intracranial compliance (amplitude of 50-100 mm Hg); occur for 5-10 min
- Indicate low CPP and ischemia, ominous sign for herniation

**Figure 5:** Schematic diagram depicting Lundberg A waves (intermittent sharp peaks)

## Lundberg B waves

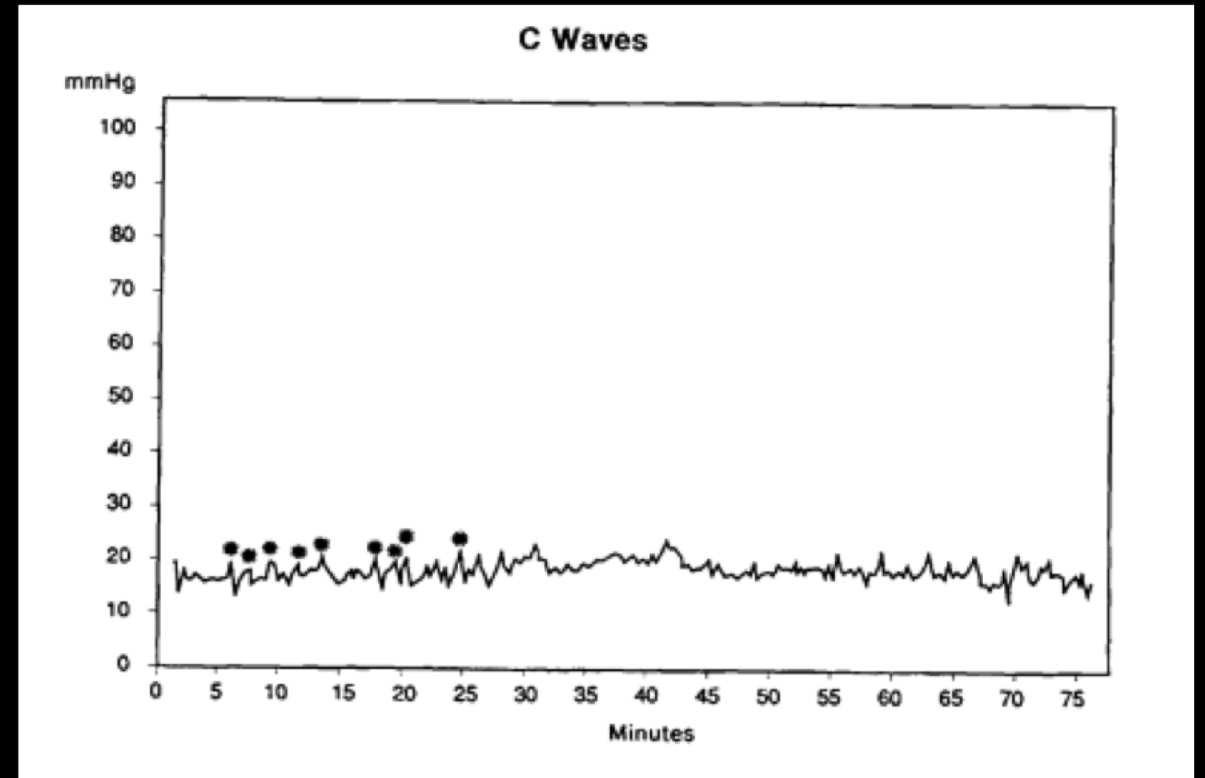

- Rhythmic oscillations, sharply peaked, occurring every 1-2 minutes; ICP increases in a crescendo manner to 20-30 mm Hg from a variable baseline, not sustained
- Reflect vasomotor changes, associated with unstable ICP

**Figure 6:** Schematic diagram showing Lundberg B waves

## Lundberg C waves

- Correspond to Traube-Hering-Meyer fluctuations in arterial pressure brought by oscillations in baroreceptor and chemoreceptor reflex control systems
- Documented in healthy adults with no clinical significance

# Methods of ICP Monitoring

- Invasive (slides below)
- Non-invasive
  - Clinical exam
  - Non-contrast head CT
  - MRI
  - Transcranial Doppler Ultrasonography
  - Tympanic Membrane Displacement
  - Optic Nerve Sheath Diameter

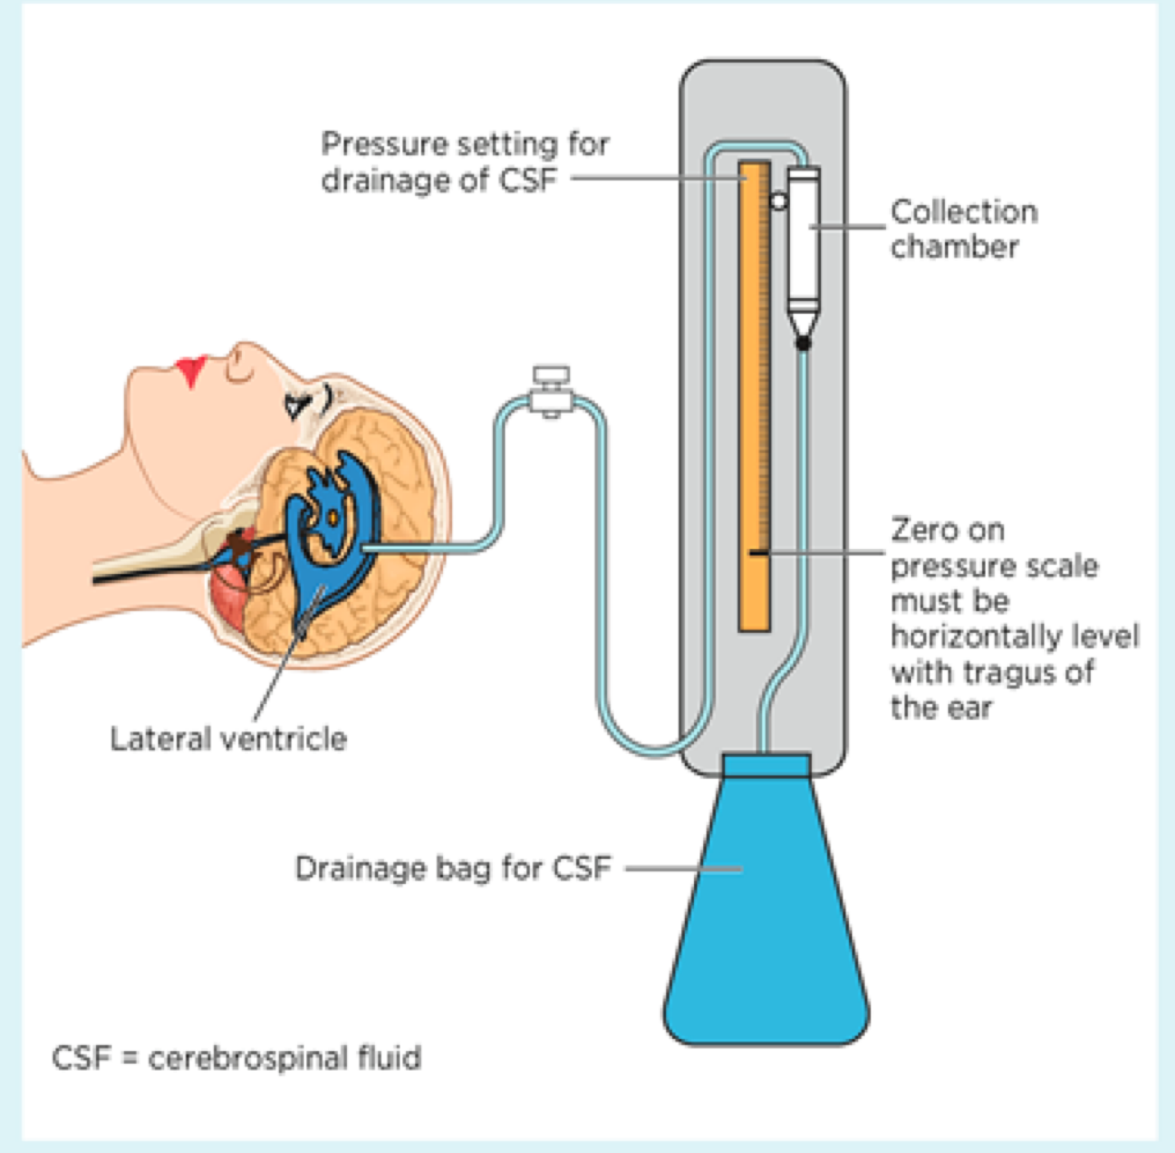

# Methods of ICP Measurement

- Location
  - Ventricular (EVD)
  - Intraparenchymal
  - Subarachnoid
  - Subdural/Extradural
  - External Fontanelle
- Technology
  - External strain gauge
  - Catheter tip
  - Strain gauge
  - Fiberoptic

# EVD

- EVD connected to external strain gauge is gold standard
- Long history, low cost, reliable
- Therapeutic and diagnostic
- Success rate ~ 82%
- Malposition 4-20%
- Hemorrhage 0-15%

Fig 2. External ventricular drain

- Intraparenchymal devices
  - Fiberoptic devices, e.g., the Camino ICP monitor, the Innerspace ICP monitor
  - Strain gauge devices, e.g., the Codman MicroSensor, the Raumedic Neurovent P ICP sensor, and the Pressio sensor

## Fibreoptic ICP monitor

- Catheter tip measures the amount of light reflected off a pressure sensitive diaphragm
- Intraparenchymal Camino ICP monitor
  - Ease of insertion – Right frontal
  - Also in the region with pathology
  - Can be inserted in severely compressed ventricles or those with midline shift
  - Low risk of hemorrhage and infection
  - Zero drift: Recalibration cannot be performed
    - 2 mm Hg (first 24 hrs); 1 mm Hg (first 5 days) – Manufacturer
    - 0.5 – 3.2 mm Hg drift - Actual

## Miniature Strain Gauge

- Codman MicroSensor ICP Transducer
  - Microchip pressure sensor at the tip of a flexible nylon cable that produces different electricity based on pressure
    - Intraventricular (Correlation coefficient 0.97 with EVD, Drift 0.2 mm Hg)
    - Intraparenchymal (Less accurate)
    - Subdural space (Not enough studies)

- Spiegelberg Parenchymal Transducer
  - Air pouch at the tip that is maintained at constant volume
  - Pressure transducer located in ICP monitor
  - Recalibration can be made easily
  - Good correlation with ICP measured by ventriculostomy
